Abstract

In the present study a list of the aphid species recorded in Greece is provided. The list includes records before 1992, which have been published in previous papers, as well as data from an almost ten-year survey using Rothamsted suction traps and Moericke traps. The recorded aphidofauna consisted of 301 species. The family Aphididae is represented by 13 subfamilies and 120 genera (300 species), while only one genus (1 species) belongs to Phylloxeridae. The aphid fauna is dominated by the subfamily Aphidinae (57.1 and 68.4 % of the total number of genera and species, respectively), especially the tribe Macrosiphini, and to a lesser extent the subfamily Eriosomatinae (12.6 and 8.3 % of the total number of genera and species, respectively). The number of species recorded in Greece is much lower than that in European countries, including those from the Mediterranean basin, where the aphid fauna is well investigated. Thus, we believe that with further research the recorded Greek aphidofauna will be substantially increased.

Key words: Aphidoidea, Hemiptera, Greece, aphid fauna.

Introduction

The study of the Greek aphidofauna was very limited, at least since the early 90s. Remaudière (1982) and Lykouressis and Tsitsipis (1987) reported 133 species in their review papers about the Greek aphidofauna. Three additional species were reported by Panayotou and Katis (1986), Katsoyannos *et al.* (1989) and Lykouressis and Polatsidis (1990). Later, Lykouressis *et al.* (1992), Lykouressis *et al.* (1993) and Katsoyannos (1994) reported 20, 23 and 23 new aphid species. However, five species were shared in the latter two studies. Thus, the total number of aphid species recorded so far in Greece come up to 195. This number is much lower compared with records in other European countries. Patti and Barbagallo (1998; see also references there in) reviewed the data of aphid species recorded in European countries, including some from the Mediterranean basin. The authors reported that the numbers of species ranged from about 600 to 850. Although some of the data reviewed by Patti and Barbagallo (1998) were rather old, the number of species is 3-4 fold higher than that reported in Greece until 1993.

Improvement on the knowledge of the Greek aphidofauna is useful in order to evaluate the importance of the species as crop pests, either due to direct or indirect damages via virus transmission, and to improve, therefore, crop protection schemes. Taking these into account, three research projects on aphids, which were performed in the previous decade, focused among others on the survey of

aphid fauna. In this paper we present a detailed list of aphid species, which has been based on previous records and on data of winged aphid captures from the Greek network of Rothamsted suction traps and Moericke traps.

Materials and methods

The Greek network of suction traps consisted of five traps in different regions, i.e. Agricultural Farm of the Aristotle University of Thessaloniki (AUT) (Mikra, Thessaloniki, 40.30 N), Agricultural Farm of the University of Thessaly (UT) (Velestino, Magnesia, 39.23 N), Agricultural Farm of the Agricultural University of Athens (AUA) (Kopais, Voiotia, 38.26 N), Farm of the Institute of Horticulture and Viniculture (Pyrgos, Peloponnese, 37.38 N) and Lasithi Plateau, Crete (35.07 N). In the first four areas the altitude is low, approximately at sea level, while Lasithi Plateau is at an elevation of 850 m. The traps in AUT, UT and AUA operated for seven years (1993-1999), while in Pyrgos and Lasithi for four (1996-1999) and two (1998-1999) years, respectively. In addition, Moericke traps were established in various crops and regions during the period 1993-2001 (figure 1).

The collected winged aphids were stored in vials filled with two volumes of ethanol (95%) and one volume of lactic acid 75% w/w (Eastop and van Emden, 1972) until species identification. The identification was based on the keys described by Jacky and Bouchery (1980), Taylor

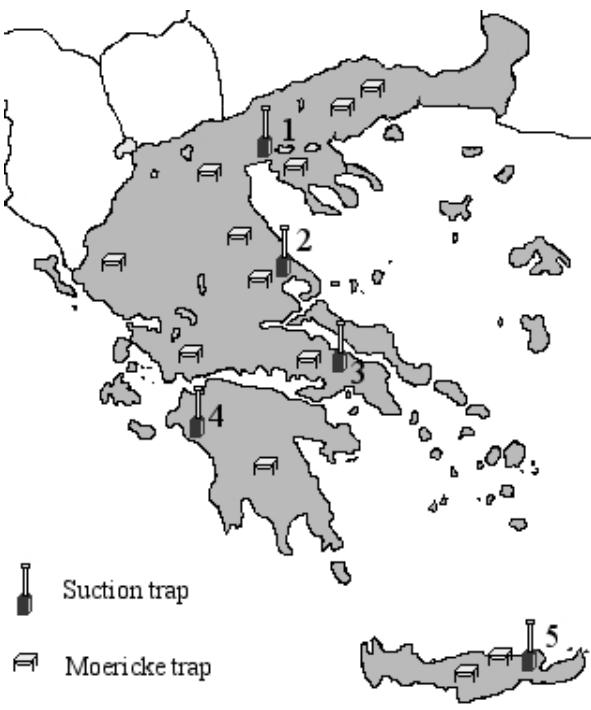

Figure 1. Location of the Rothamsted suction traps and Moericke traps. 1: Agricultural Farm of the Aristotle University of Thessaloniki, Mikra, Thessaloniki (185 species). 2: Agricultural Farm of the University of Thessaly, Velestino, Magnesia, (145 species). 3: Agricultural Farm of the Agricultural University of Athens, Kopais, Voiotia (159 species). 4: Farm of the Institute of Horticulture and Viniculture, Pyrgos, Peloponnese (132 species). 5: Lasithi Plateau, Crete (86 species). Numbers in brackets denote number of species captured in each suction trap during the whole surveying period.

(1984) and Remaudière and Seco Fernández (1990). We used the aphid classification system proposed by Remaudière and Stroyan (1984) and used by Remaudière and Remaudière (1997) in the catalogue of world's aphids. This classification system has been followed also by other authors (e.g. Blackman and Eastop, 1994), although with some revision of subfamilies names (Nieto Nafria *et al.*, 1998; Blackman and Eastop, 2000; Fauna Europaea Web Service, 2005). These revisions have been followed also in the present paper.

Results and discussion

Table 1 summarises the recorded Greek aphidofauna and table 2 shows the detailed list of the species. Both tables have been based on previous records and on the data of captures from suction and Moericke traps during the 10-year surveying period. One hundred and thirteen species are new records in Greece and therefore, the total number of known species comes up to 301. During this survey other taxa have been captured, but they were identified only at the genus level and, therefore, are not included in the list. The family Aphididae is represented by 13 subfamilies and 120 genera (300 species), while only one

genus (1 species) is recorded in Phylloxeridae. The recorded fauna is dominated by the subfamily Aphidinae (57.1 and 68.4 % of the total number of genera and species, respectively), especially the tribe Macrosiphini, and to a lesser extent the subfamily Eriosomatinae (12.6 and 8.3 % of the total number of genera and species, respectively).

The predominance of Aphidinae may be explained by the fact that all suction traps were located in agricultural areas inside farms. This subfamily includes the majority of agricultural aphid pest species as well as of species colonizing wild flora (either herbs or shrubs). It is probable that the location of the suction traps has biased somehow the composition of the species recorded, because, for example, the chances of forest species to be captured were reduced. It is well known that most aphid species live on vascular plants and the infestation causes direct and/or indirect damages *via* virus transmission. Among the aphid fauna recorded about 48% of the species may infest cultivated crops and ornamental plants. However, fewer species, probably not more than 15%, could be considered perhaps as tentative or important pests. For example, various Aphidinae species cause severe damages in herbaceous crops (e.g. *Myzus persicae* s.lat., *Aphis gossypii* Glover, *Aphis fabae* Scopoli) or trees (e.g. *Dysaphis plantaginea* (Passerini)). Very few belong to other subfamilies such as the woolly apple aphid *Eriosoma lanigerum* (Hausmann) (Eriosomatinae). The importance of various aphid species in the epidemiology of non-persistent viruses in Greece has been highlighted in several studies (e.g. Katis *et al.*, 1998; 2006; Kanavaki *et al.*, 2006). Lastly, there are also studies demonstrating the development of resistance to various classes of insecticides by some species, e.g. *M. persicae* (Cox *et al.*, 2004; Margaritopoulos *et al.*, 2007).

Table 1. Summary of the aphid fauna of Greece.

FAMILIES / Subfamilies	Tribes	No. genera	No. species
APHIDIDAE

PHYLLOXERIDAE

Genus (Subgenus) species subspecies	Genus	Tribe-Subtribe	Subfamily
<i>Viteus vitifoliae</i> (Fitch)	<i>Viteus</i> Shimer	—	—

Looking at the regional variation in the number of species recorded, a comparison could be made among the five localities where the suction traps operated. The highest number of species (185) was recorded in the north, in Mikra near Thessaloniki, while the lowest in the southern regions, Pyrgos, Peloponnese (132) and Lasithi, Crete (86). There is a significant correlation between latitude and number of species (Pearson's correlation = 0.95, P< 0.05), which might suggest that the Greek aphidofauna follows the general trend, i.e. fewer species as we gradually move from North to South (Dixon *et al.*, 1987).

From a systematic point of view the Greek aphidofauna does not show special characteristics and it consists of species already known in other European countries including those from the Mediterranean basin. There is one exception, however: the grapevine aphid *Aphis illinoiensis* Shimer. It is a North American species, which has been recorded in various localities in Crete Island in the summer of 2005 (Tsitsipis *et al.*, 2005). Previously, the species had invaded Turkey (Remaudière *et al.*, 2003). It is worth noticing that regardless of the improvements in the knowledge in aphidofauna made in Greece during the last decade, the total number (301) of species recorded is much lower than that found in well investigated European countries. For example, in Italy and France 760 (Patti and Barbagallo, 1998) and 700 (Dixon *et al.*, 1987; Remaudière personal communication in Patti and Barbagallo, 1998) species have been reported respectively. Also, in a neighbouring country, Serbia, the number of species found (341) is higher than that in Greece (Petrović-Obradović, 2003). In Serbia, however, a slightly lower number of genera was reported compared to Greece (108 vs. 121). The Greek territory runs from the subtropical arid climate (southern areas of Crete Island) to the medium temperate areas of the northern regions and climate, orography and ecological habitats are quite diverse. In addition, the flora diversity is rather high in Greece with the number of species estimated between 4,900 and 5,500 (Strid and Tan, 1991; Sfikas, 1997). These suggest that with further research the recorded aphid fauna will be substantially increased. Conclusively, the ten-year survey enriched our knowledge on the Greek aphidofauna. However, the survey should be continued, especially in non investigated areas and in relation to the aphid host plants or trees.

Acknowledgements

The present work was funded in great part by the General Secretariat for Research and Technology of Greece through the STRIDE HELLAS 143 and EPET II 453 research projects and to a lesser extent, by Commission of the European Communities, Tobacco Information and Research Fund, project 96/T/18 'Management of the insect pests and viruses using ecologically compatible technologies'. The authors thank Mrs E. Panagiotaki and Mrs N. Tomara for their help in aphid identification. Lastly, the authors thank the two anonymous reviewers for their valuable comments.
